

# Building REST APIs with Spring Boot

## 3.2 Creating REST Endpoints

# Learning objectives

---

- ▶ Introduction to REST Controllers
- ▶ Understanding @RestController and @RequestMapping
- ▶ Creating simple GET endpoints
- ▶ Handling path and query parameters
- ▶ Returning JSON responses

# What Is a REST Controller?

---

- ▶ Spring component that handles HTTP requests and responses
- ▶ Defined using the `@RestController` annotation
- ▶ Combines `@Controller` + `@ResponseBody`
- ▶ Automatically converts Java objects to JSON via Jackson
- ▶ Forms the backbone of RESTful APIs in Spring Boot

# Learning objectives

Annotation	Purpose
<b>@RestController</b>	Marks class as REST API controller
<b>@RequestMapping</b>	Maps base URI path for all endpoints
<b>@GetMapping, @PostMapping, etc.</b>	Shortcut for specific HTTP methods
<b>@PathVariable</b>	Extracts variables from URL path
<b>@RequestParam</b>	Reads query parameters
<b>@RequestBody</b>	Binds request JSON body to Java object

# Remember the tweet about Spring Boot?

- ▶ This is kind of what we will create now

**Rob Winch**

@rob\_winch

@Controller

```
class ThisWillActuallyRun {  
    @RequestMapping("/")  
    @ResponseBody  
    String home() {  
        "Hello World!"  
    }  
}
```

# Demo - Building a Simple REST API with Spring Boot

---

- ▶ Demonstrate key Spring Boot REST features
- ▶ Show how controllers expose endpoints
- ▶ Introduce JSON request/response handling
- ▶ Use simple Person objects as the domain
- ▶ Cover GET, POST, and PATCH
- ▶ Test endpoints using Postman or browser

# What the Demo Will Show

---

- ▶ Returning JSON objects with `@RestController`
- ▶ Mapping HTTP methods with annotations
- ▶ Using `@PathVariable` for dynamic URLs
- ▶ Using `@RequestParam` for optional query parameters
- ▶ Creating new resources with POST
- ▶ Updating part of a resource with PATCH

# Using @PathVariable and @RequestParam

---

- ▶ Path variables appear in the URL
- ▶ Query parameters come after "?"
- ▶ Path variables identify a specific resource
- ▶ Query parameters refine/filter data
- ▶ Browser can call both patterns
- ▶ Very common in real APIs

# Lab – Building Your Own Task API

---

- ▶ Goal: Build a small REST API for managing simple tasks.
- ▶ You will create endpoints to:
  - ▶ Return a list of tasks
  - ▶ Return one task
  - ▶ Create a task with POST
  - ▶ Toggle task completion with PATCH
  - ▶ Work with JSON input and output

# Lab Domain – Task

---

- ▶ Each task has:
  - ▶ id (int)
  - ▶ title (String)
  - ▶ completed (boolean)
- ▶ Use an in-memory list during this lab.

# Lab – Required Endpoints

---

- ▶ 1. GET /api/tasks  
Return all tasks
- ▶ 2. GET /api/tasks/{id}  
Return a single task
- ▶ 3. POST /api/tasks  
Create a new task
  - ▶ JSON body: { "title": "Learn Spring" }
- ▶ 4. PATCH /api/tasks/{id}/toggle  
Flip completed from true → false or false → true

# Lab Instructions

---

- ▶ 1. Create a Spring Boot project
- ▶ 2. Create a Task model class
- ▶ 3. Create a controller in /api/tasks
- ▶ 4. Maintain an in-memory list of tasks
- ▶ 5. Implement GET, POST, and PATCH endpoints
- ▶ 6. Start the application and test all endpoints
- ▶ 7. Verify JSON responses in your browser or Postman

# Lab - Optional Challenge

---

- ▶ Add extra functionality:
- ▶ Support searching tasks by ?completed=true
- ▶ Add an auto-incrementing ID generator
- ▶ Prevent empty task titles

# Lab Summary

---

- ▶ After completing this lab, you will understand:
  - ▶ Core controller mechanics
  - ▶ JSON input (POST) and partial updates (PATCH)
  - ▶ Managing simple state in memory
  - ▶ REST endpoint structure and naming conventions

# Key Takeaways

---

- ▶ `@RestController` is the entry point for all REST APIs
- ▶ Annotations like `@GetMapping`, `@PostMapping` and `@PatchMapping` to map HTTP methods to Java methods.
- ▶ Annotations like `@RequestParam` and `@PathVariable` for input
- ▶ Spring Boot auto-converts Java objects into JSON
- ▶ You've just created your first working REST API!
